

***Let me start with some  
introduction  
&  
get to know you the table of  
contents here***

# TABLE OF CONTENTS

- File Systems
- Different types of file operations
- Working with Directories in PHP
- Operations of Directories

# File Systems :

PHP File System allows us to create file, read file line by line, read file character by character, write file, append file, delete file and close file.

# To open a file

➤ The PHP fopen() function is used to open a file.

➤ **Syntax :**

```
fopen("$file_name", "r");
```

# To close a file

➤ The PHP fclose() function is used to close an open file pointer.

➤ Syntax :

```
fclose($file_handle);
```

# To Read a file

➤ The PHP fread() function is used to read the content of the file. It accepts two arguments : resource and file size.

➤ Syntax :

```
fread($handle, filesize($file_name));
```

➤ To print the data from the file we read : [ echo \$contents; ]

5  ?>
6
```

# To Write a file

➤ The PHP fwrite() function is used to write content of the string into the file.

➤ Syntax :

```
fwrite($handle, string of content );
```

# MODE & PURPOSE

<b>r</b>	Opens the file for reading only. Places the file pointer at the beginning of the file.
<b>r+</b>	Opens the file for reading and writing. Places the file pointer at the beginning of the file.
<b>w</b>	Opens the file for writing only. Places the file pointer at the beginning of the file and truncates the file to zero length. If files does notexist then it attempts to create a file
<b>w+</b>	Opens the file for reading and writing only. Places the file pointer at the beginning of the file and truncates the file to zero length. If files does notexist then it attempts to create a file.
<b>a</b>	Opens the file for writing only. Places the file pointer at the end of the file. If files does not exist then it attempts to create a file.
<b>a+</b>	Opens the file for reading and writing only. Places the file pointer at the end of the file. If files does not exist then it attempts to create a file.

# PARSING DIRECTORIES

~ IN PHP

# Working with Directories in PHP

## Directory :

- ❑ *A directory is a file system*
- ❑ *It is a Cataloging structure*
- ❑ *Contains references to other computer files and other directories and sub-directories*
- ❑ *Known as folders !*

# Operations of Directory:

- ✓ Creating a directory
- ✓ Opening a directory
- ✓ Reading a directory
- ✓ To Delete a directory
- ✓ List all files in the Directory

# Creating a new Directory

- Use mkdir() function with the path and name of the directory.

➤ **Syntax :**

```
mkdir($directory_path);
```

- **\$directory\_path:** either relative and absolute path (location) if it wrong will return an error.
- The function returns boolean data, that is, true on successful execution, false otherwise.
- The name mkdir stands for "make directory".

2  // The directory path
3  $dir = "testdir";
4
5  // Check the existence of directory
6  if(!file_exists($dir)){
7      // Attempt to create directory
8      if(mkdir($dir)){
9          echo "Directory created successfully.";
10     }
11     else{
12         echo "ERROR: Directory could not be created.";
13     }
14 } else{
15     echo "ERROR: Directory already exists.";
16 }
17 ?>
18
19
20
21
```

# Closing Directory Link

➤ To close this link after completing to the related functions.

➤ **Syntax :**

```
closedir($directory_handle);
```

## OPEN EDITORS

2      // opening a directory
3      |   $dir_handle = opendir("c");
4      // reading the contents of the directory
5
6      while(($file_name = readdir($dir_handle)) !== false)
7      {
8          |   echo("File Name: " . $file_name);
9          |   echo "<br>" ;
10     }
11     // closing the directory
12     closedir($dir_handle);
13 ?>
```

# Reading Directory

- Use **readdir()** function.

➤ **Syntax :**

```
readdir(dir_handle);
```

- Returns the filenames in the order as they are stored in the directory.
- Returns the entry name/filename on success or false on failure
- Use with loop.
- **dir\_handle:** a mandatory parameter, specifies the handling resource previously opened by the **opendir()** function. returns the entry name/filename on success, or false on failure

# Removing Directory

➤ **rmdir()** function use for removing directories

➤ **Syntax :**

```
rmdir($directory_path);
```

➤ **NOTE :** Function will remove the directory, if and only if it is empty. For removing the non-empty directory, use **unlink()** function.

# To Copy a file from one to other location

➤ You can copy a file from one location to another by calling PHP `copy()` function with the file's source and destination paths as arguments. If the destination file already exists it'll be overwritten. Here's an example which creates a copy of "example.txt" file inside backup folder.

➤ Syntax :

```
copy($old_file, $new_file);
```
